

IMPROVED DISTRIBUTOR CLUTCH

A new, much simpler and more sensitive distributor clutch has been designed for single distributor Linotypes.

The clutch is actuated by a new clutch lever which operates in conjunction with a toothed disk. If matrix travel on the distributor bar is interfered with, the lower distributor screw is moved to the left. This permits a spring to pull a stop on the clutch lever against the toothed disk to stop the rotation of the disk. This action disengages the friction facings from contact with the clutch pulley, thereby stopping the distributor.
